

Suspicious Traffic Identification Report

1. ARP Traffic Analysis

Observation:

- One MAC address (00:07:0d:af:f4:54) sent all the ARP requests.
- The packets were sent to the broadcast address (ff:ff:ff:ff:ff:ff).
- It was asking for many different IP addresses very quickly.

Suspicious Signs:

- Too many ARP requests coming from just one device in a short time.
- This looks like network scanning or someone trying to discover devices on the network.
- It could also be the start of an ARP poisoning attack.

Assessment

This traffic is suspicious. It is not normal for one device to send this many ARP requests so fast.

Risk Level: Medium-High

2. DNS Traffic Analysis

Observation

- Queries for normal websites like google.com, www.google.com, www.netbsd.org, and example.com.
- One reverse DNS lookup.

Suspicious Signs

- Very few suspicious signs. Just normal web browsing and name resolution.

Assessment

This looks like regular user activity. Nothing clearly malicious.

Risk Level: Low

3. HTTP Traffic Analysis (http.cap)

Observation

- Lots of multicast packets (normal for device discovery).
- No regular web page requests.

Suspicious Signs

- None. No bad websites, strange downloads, or suspicious activity.

Assessment

This appears to be normal network behavior for service discovery.

Risk Level: Low

Conclusion

The only suspicious traffic was in the ARP capture. The high number of ARP requests from one MAC address looks like network scanning or possible ARP attack preparation. The DNS and HTTP traffic looked normal.

Recommendations

- Watch out for devices sending too many ARP requests.
- Use tools like Wireshark to monitor the network.
- Consider enabling port security on switches.
